Flood Hazard

- Modeling Options
- 1D
- 2D
- 1D/2D-coupled

Example-1D

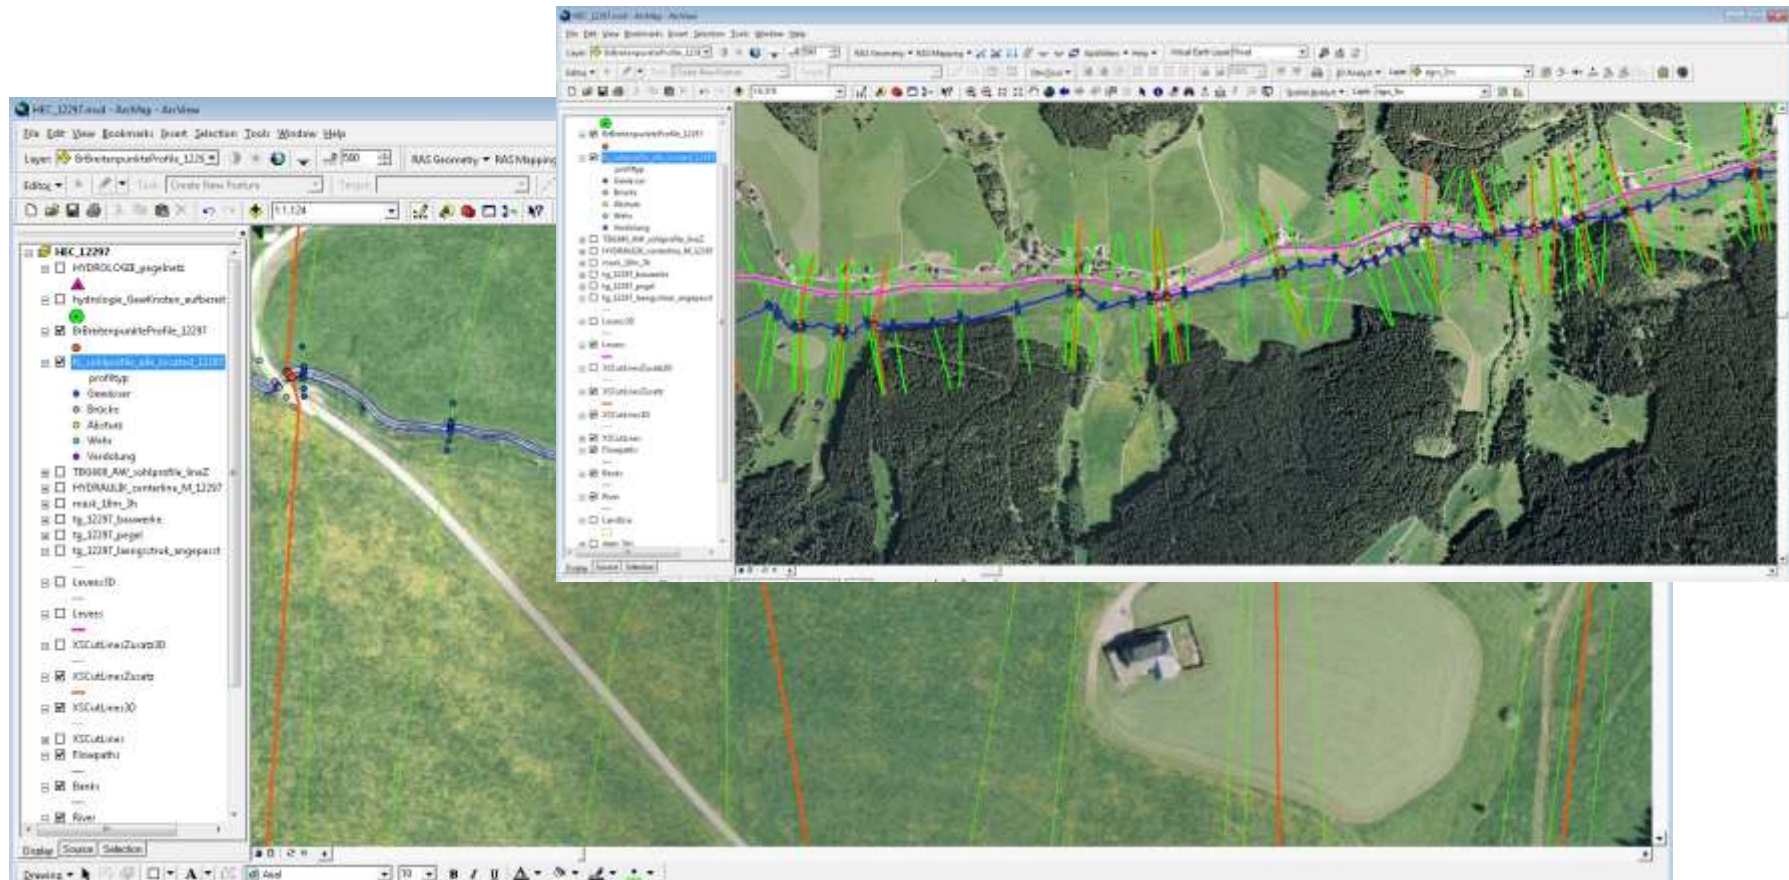

- Procedure:
 - Hydrological modeling
 - Surveying of cross sections
 - Hydraulic representation of terrain
 - 1D-Model (e.g. HEC-RAS)
 - Water level at cross sections
 - Extrapolation to area using a DTM (HEC-GeoRas)
- Result: Flood inundation (hazard map)

1D

- E.g. HecRas

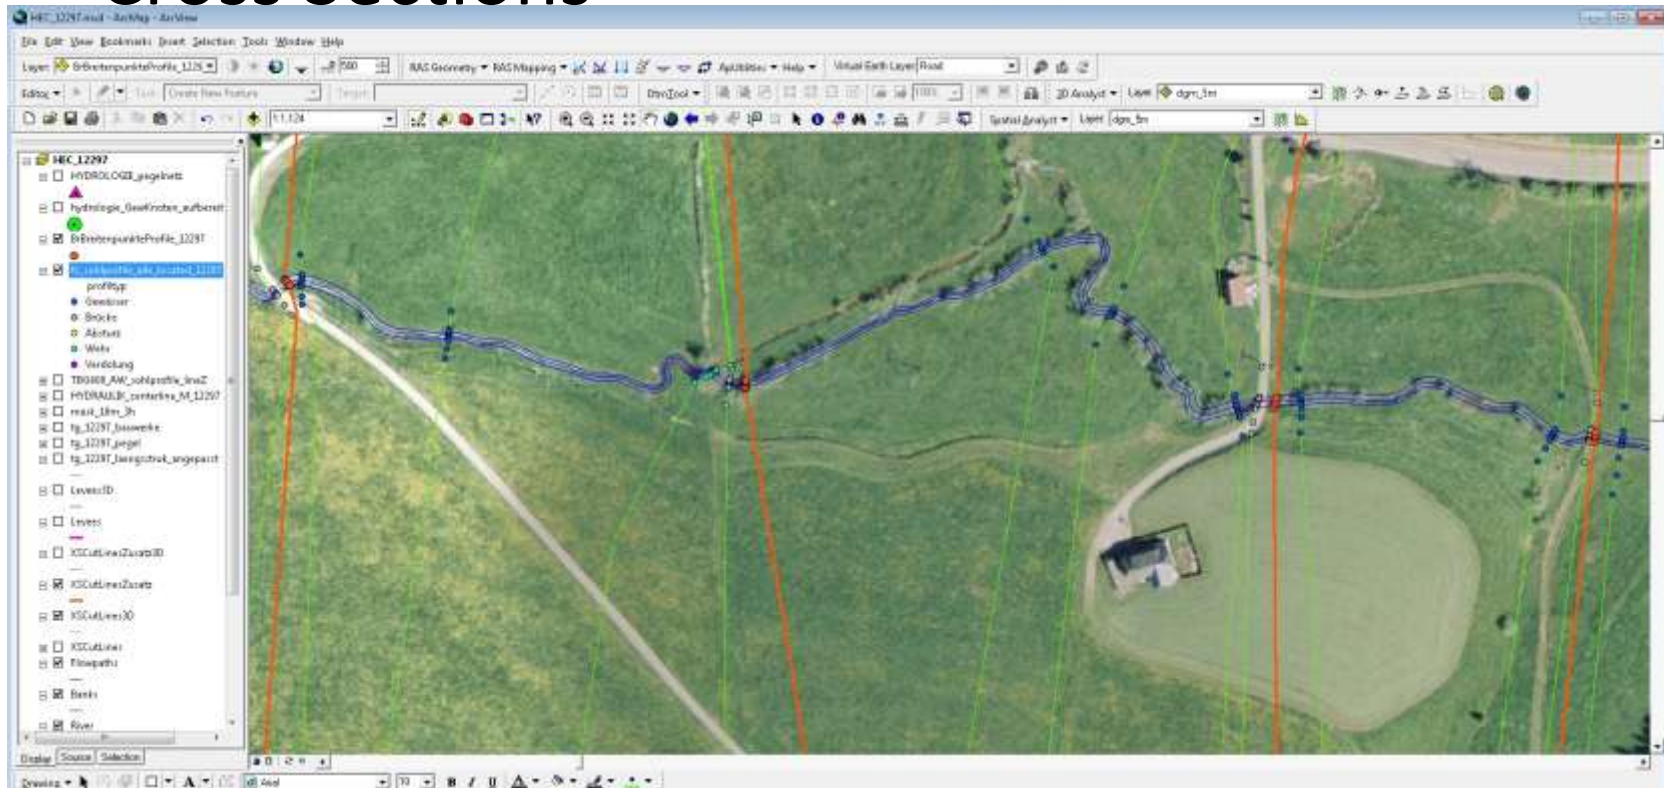

1D

- Cross Sections

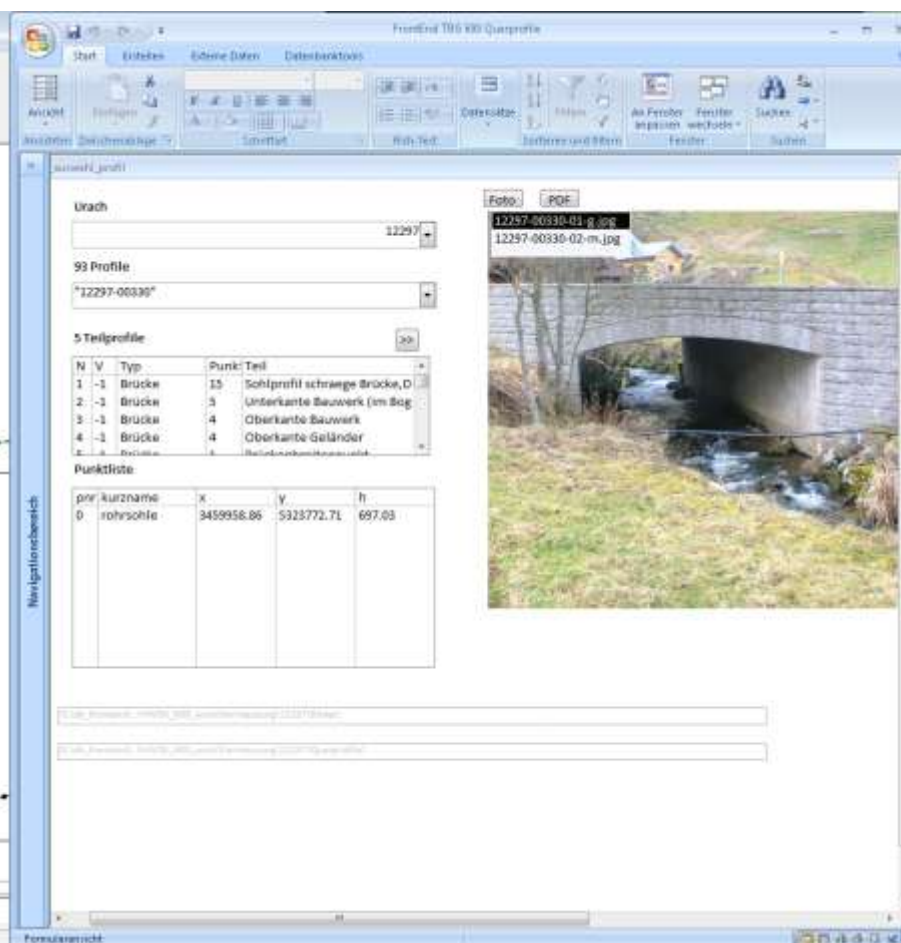

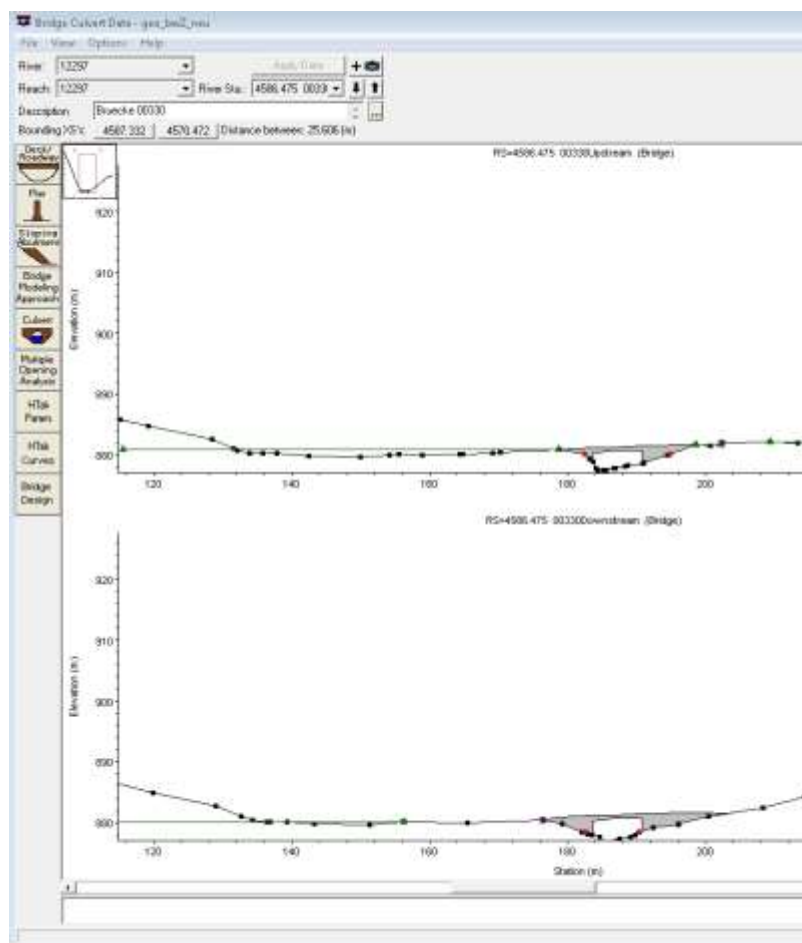

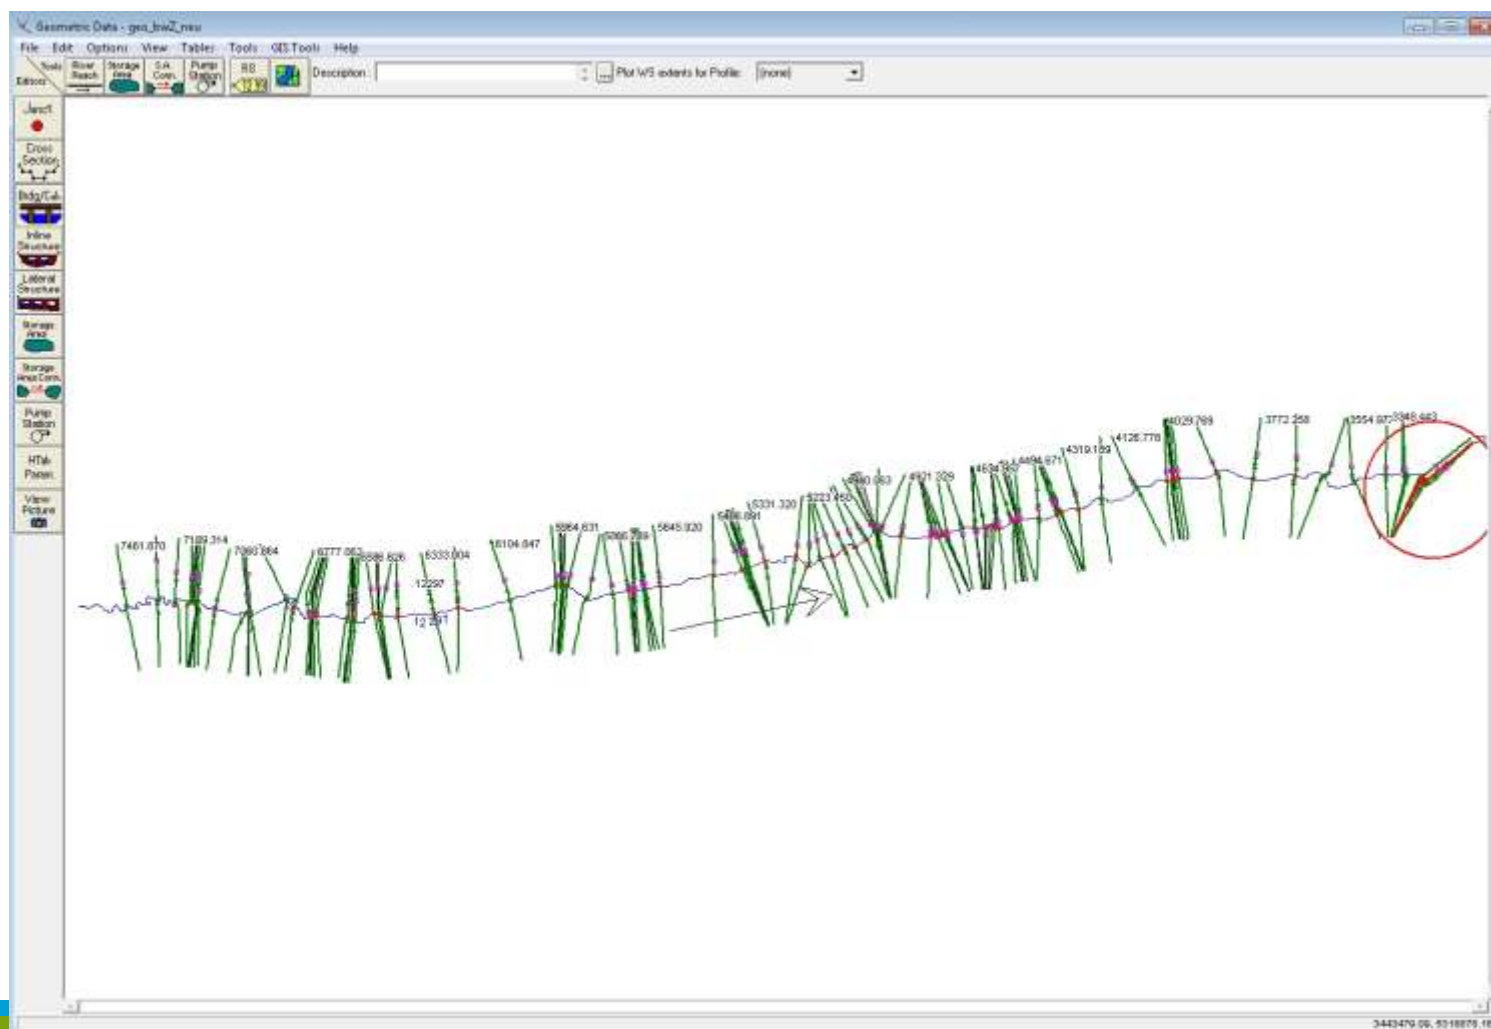

1D

- Cross Sections

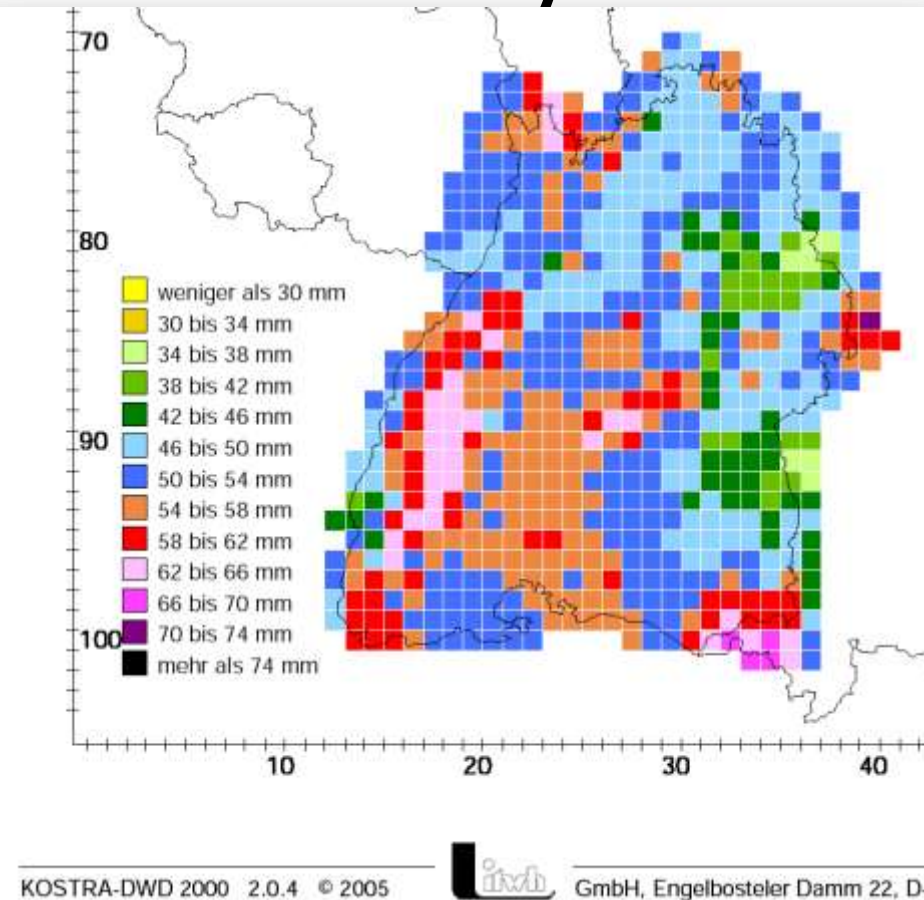

Model chain summary

Hydrological Model

- » Low resolution (1 km)
- » Low demand on computational resources

Flood Hazard Map

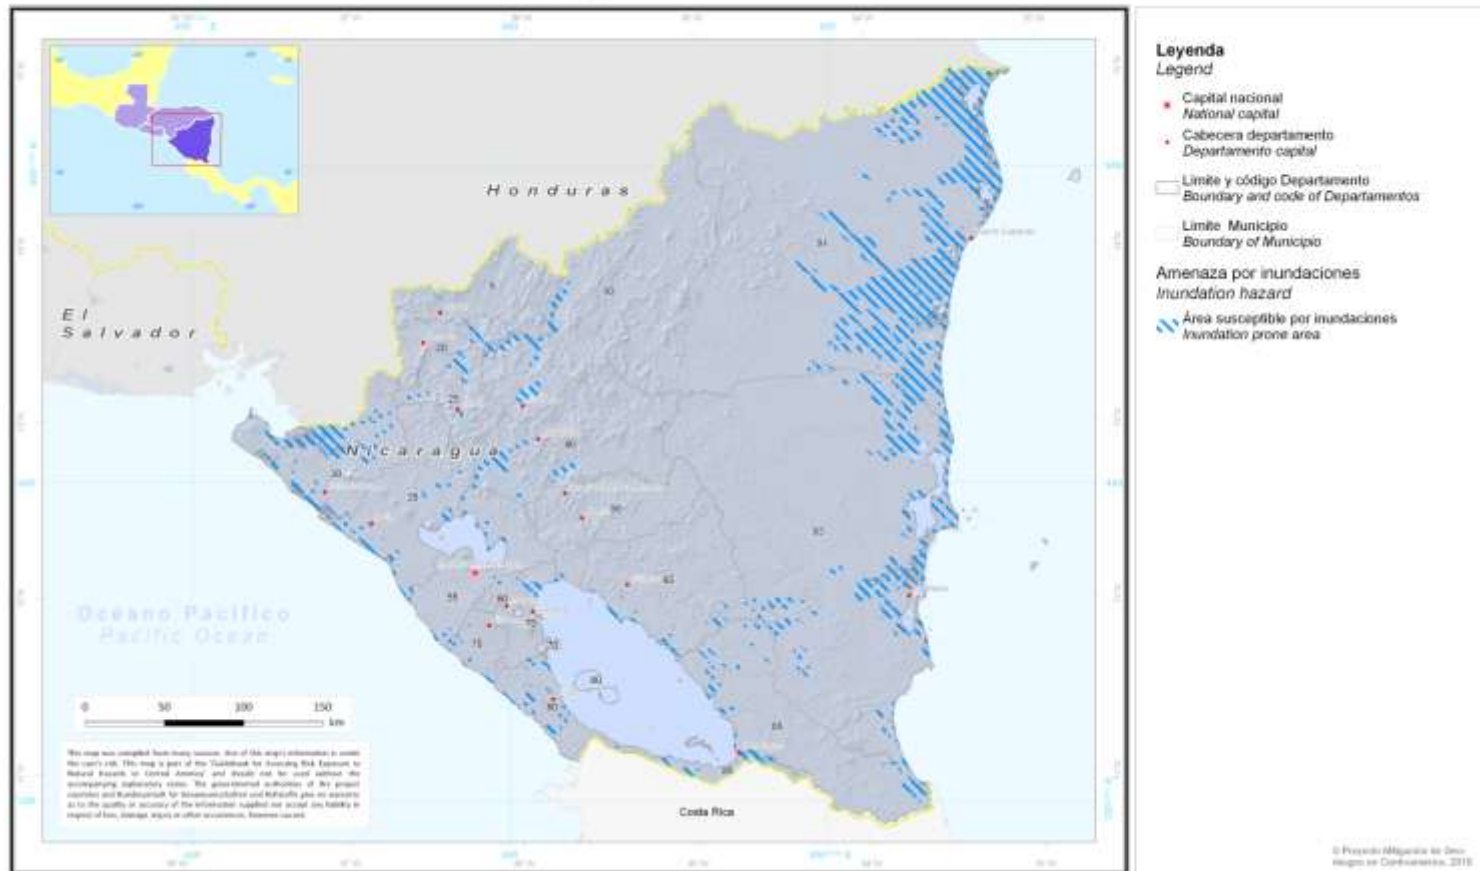

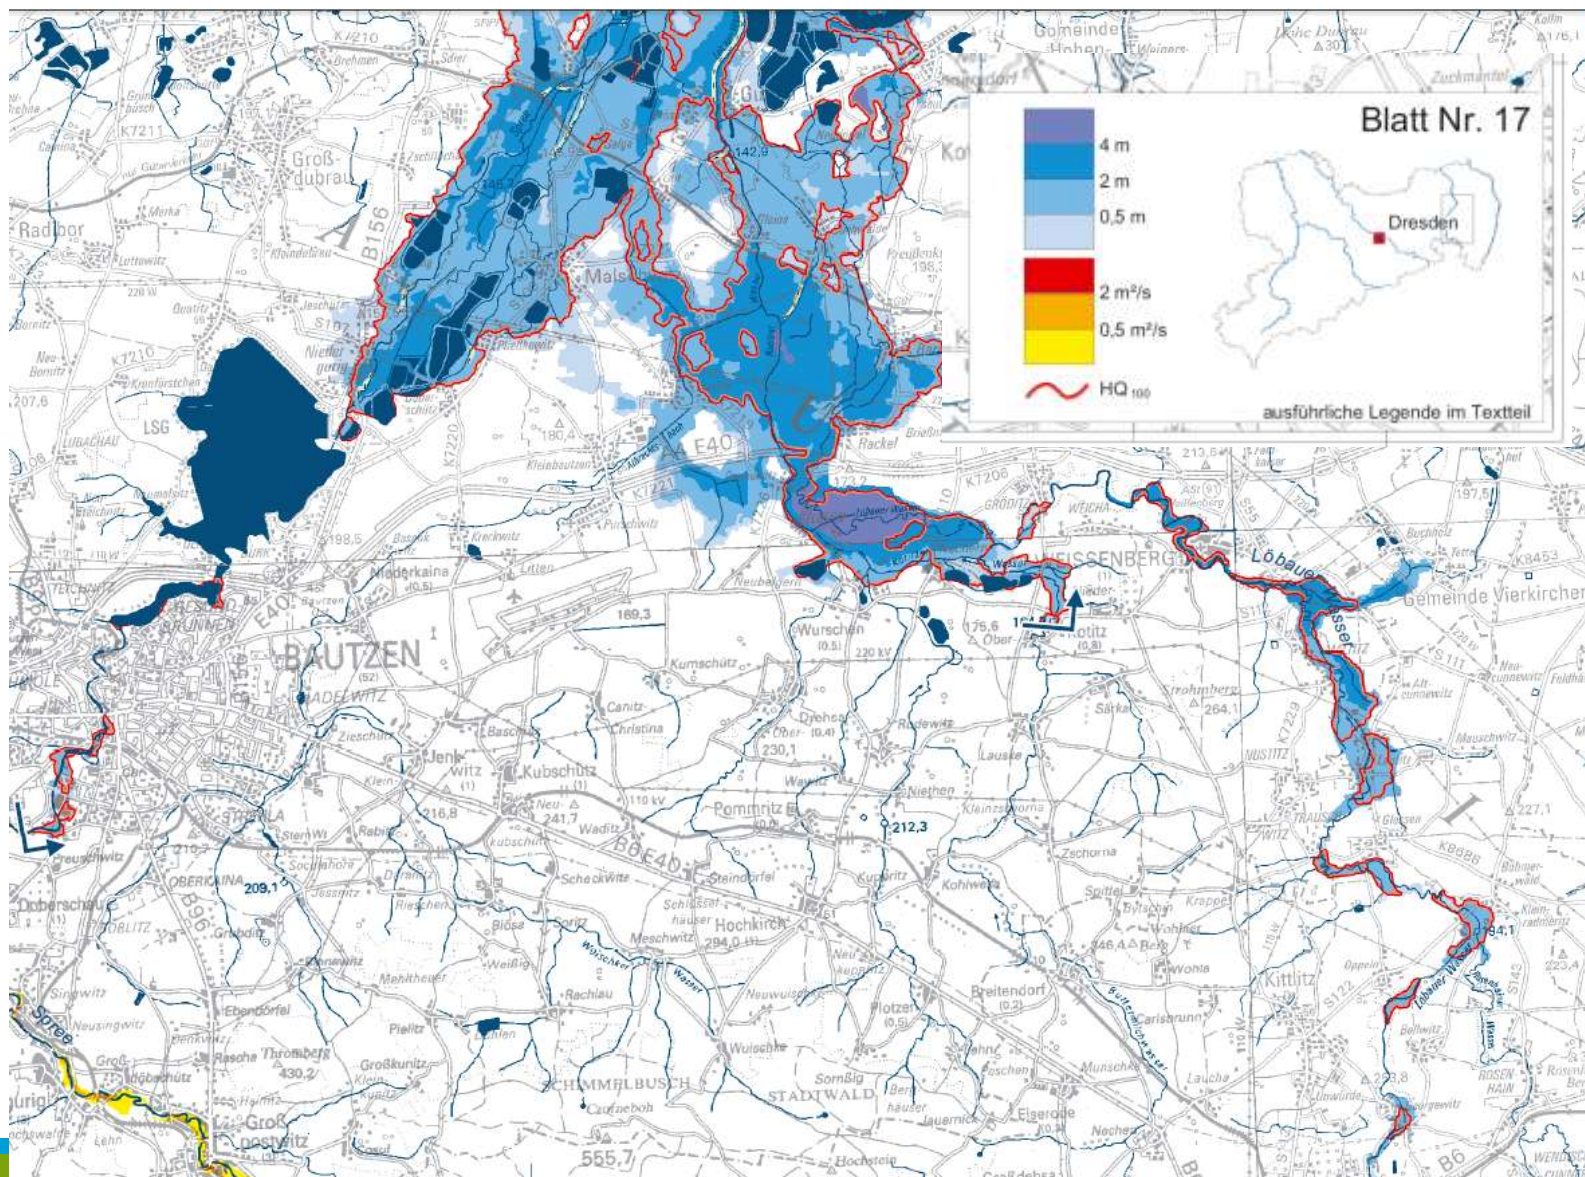

Examples

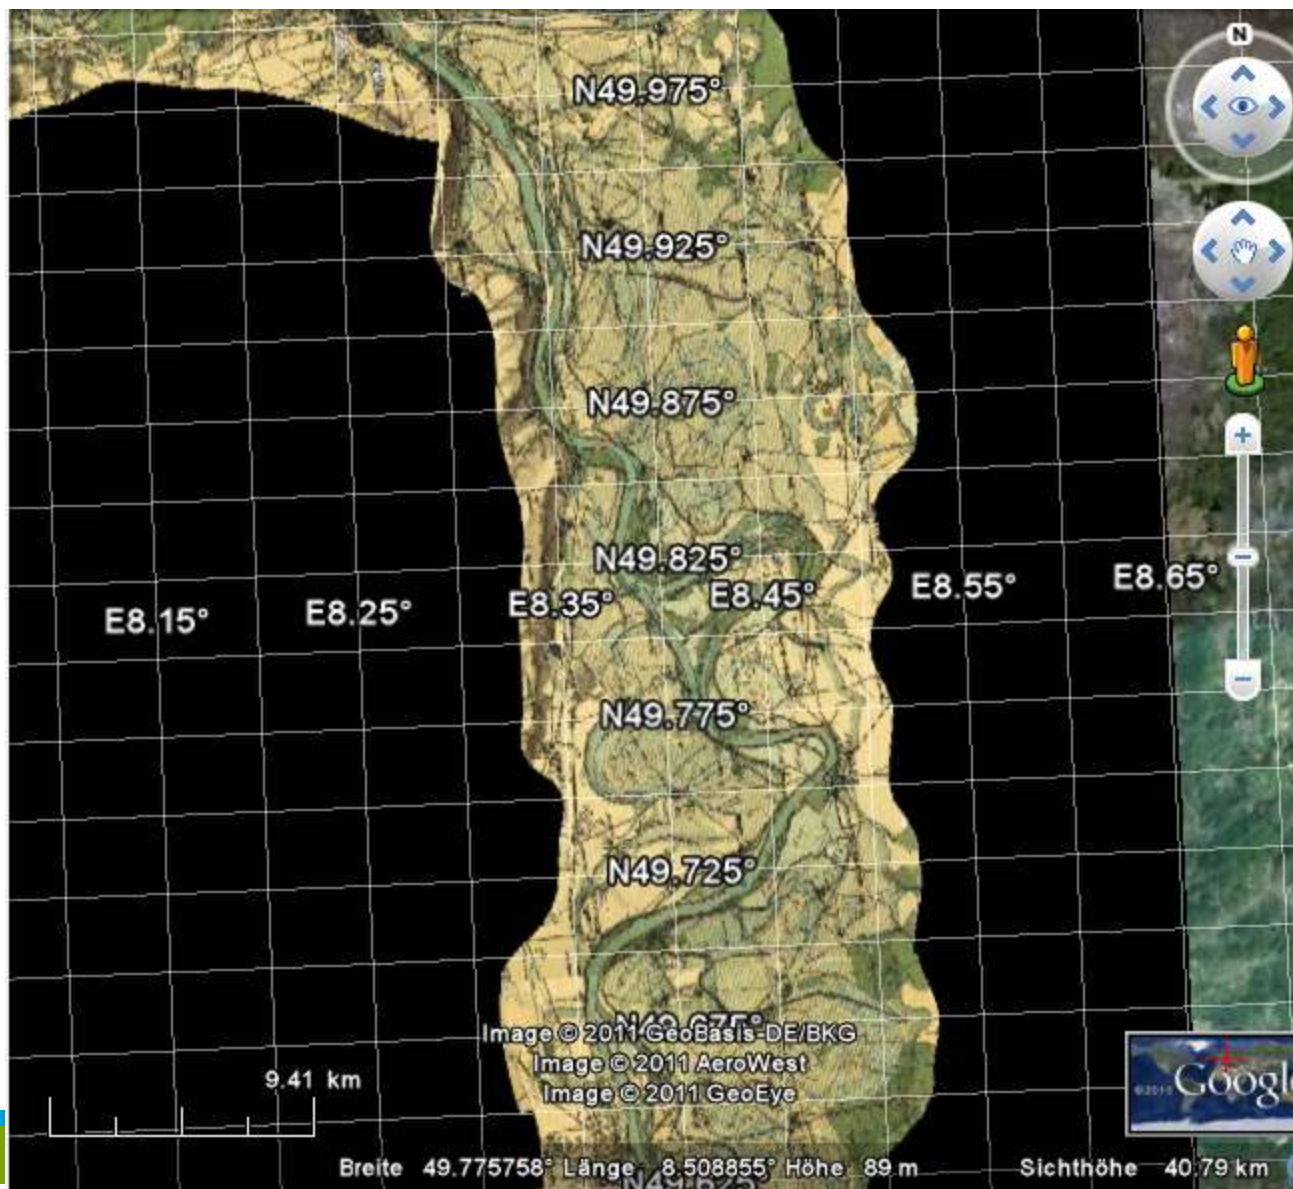

Hazard Maps

Amenaza por Inundaciones

Inundation Hazard

2D

- Computationally more demanding because of ever increasing DEM resolution

Torrential rain/ flash flood Hazard Map

- » High resolution (1m)
- » High demand on computational resources

Identifying Potential damages (Elements at Risk):

Identifying Potential damages (Elements at Risk):

1. Causes
2. Types
3. Evaluation and quantification

Flooding damages – why do we need to identify their types and dimension

- To determine their vulnerability and risk
- For cost/benefit estimates
- For better spatial planning
- For better preparedness
- For contingency planning
-

Causes: damages by example

- Parameter: water level / water pressure

Water level / water pressure

Weight of building smaller than buoyant force:
-> The building will „float“
(Damages to the stability)

Parameter: flow velocity

Glashütte / Erzgebirge 1927

Example BEAM

Basic European Assest Map
(regional to national scale)

BEAM product example Bucharest

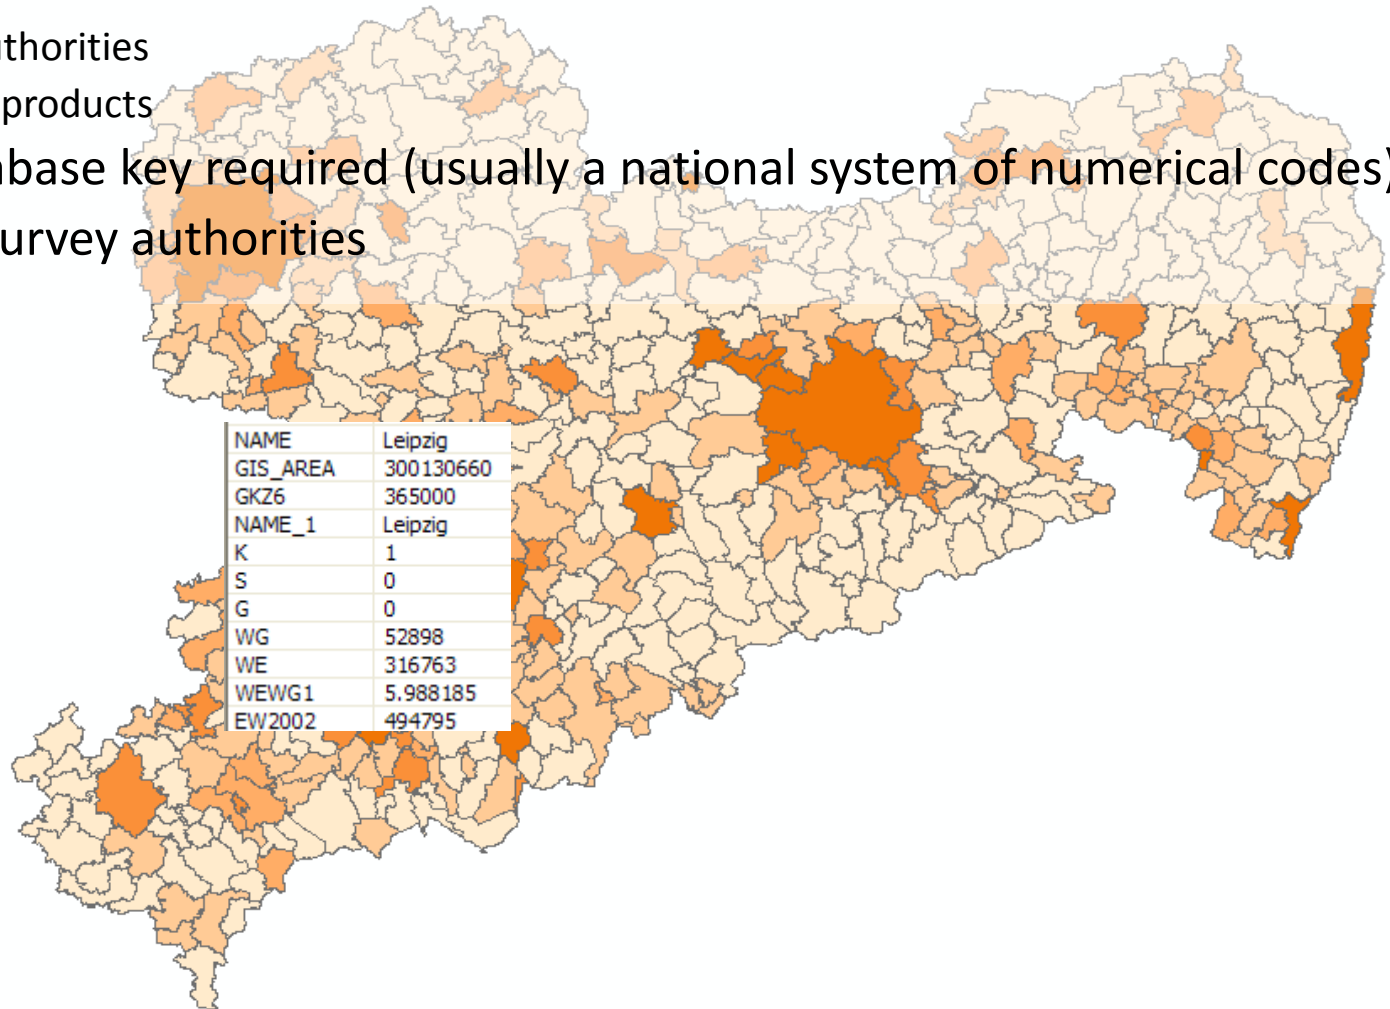

Calculation of potential damage / EAR:

- Procedure for population at risk
 - Required input data
 - Information on demographics
 - Information on administrative (sub)-division of the study area
 - Information on land use / land cover
 - Flood hazard map (inundation areas), perhaps with different probability of flooding (2yr, 5yr, 10yr, 100yr-flood etc.)
 - GIS based intersection
 - Result: count (better: statistical estimate) of potentially affected population per administrative sub-division (national, sub-national, province, county, city, etc.)

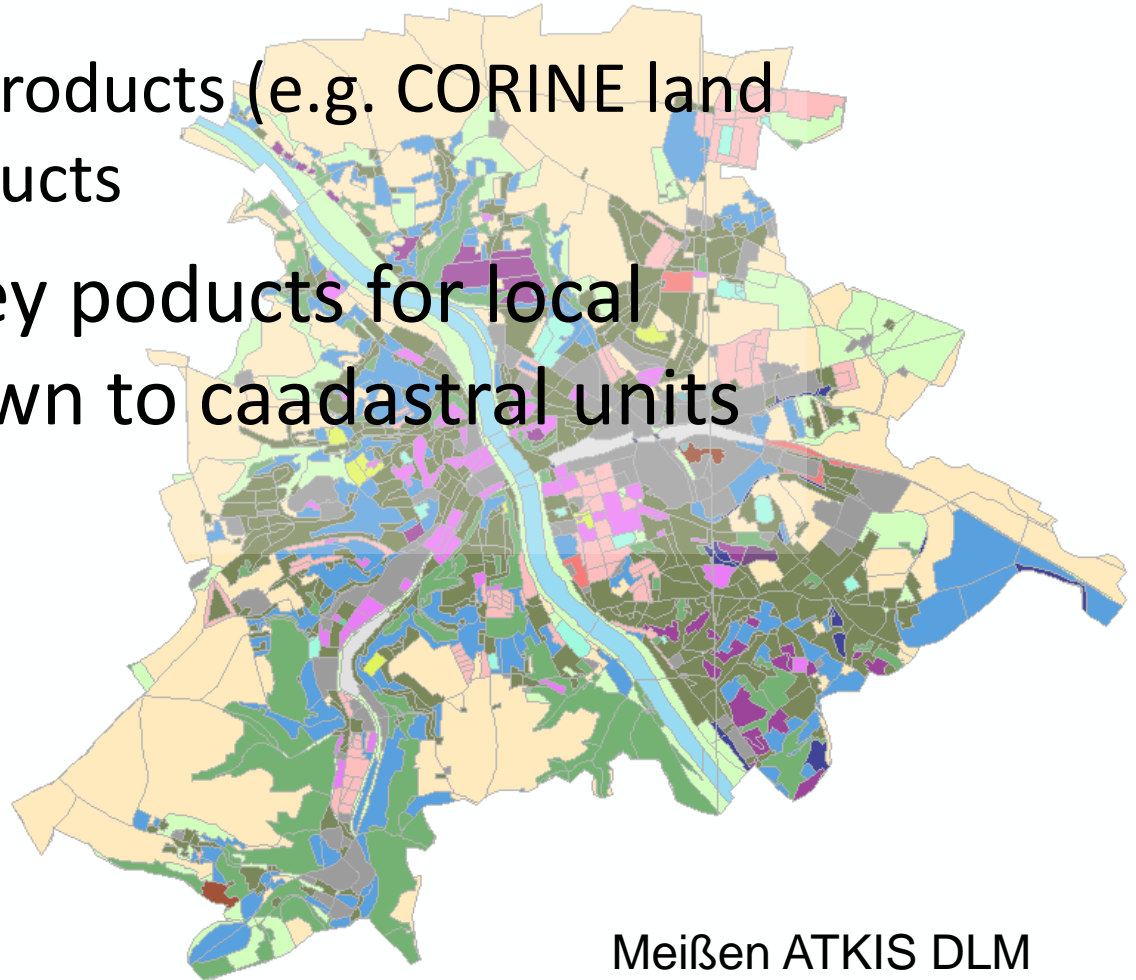

Administrative Gliederung & Demographische Daten

- Data sources:
 - Statistics authorities
 - Commercial products
- Common database key required (usually a national system of numerical codes)
- Topographic survey authorities

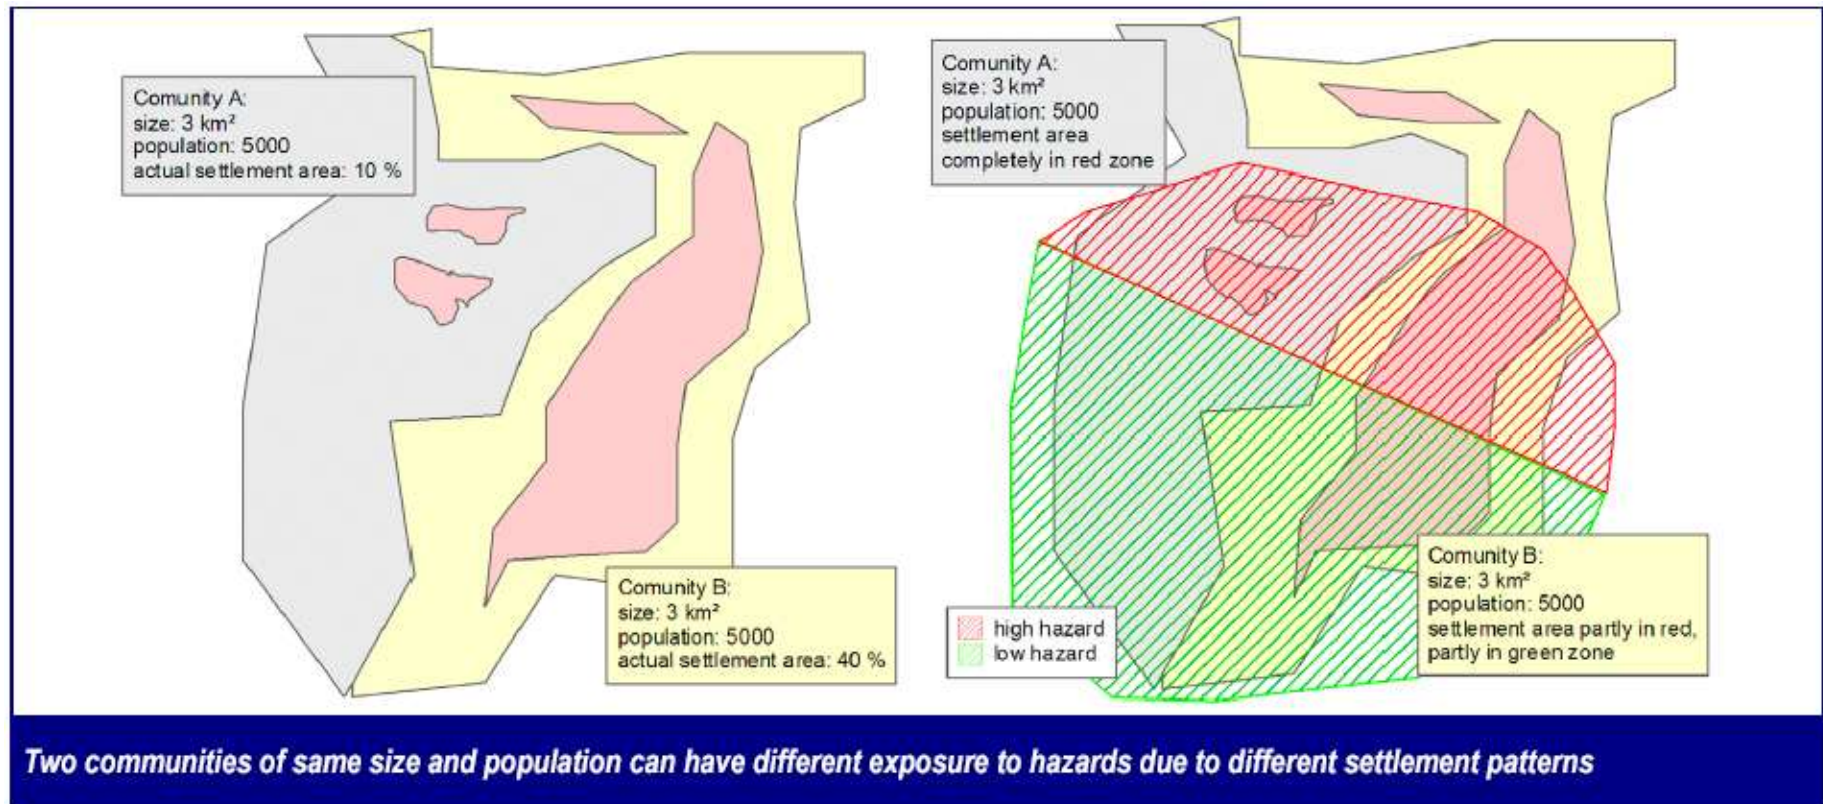

Land use / land cover

- Data sources:
 - Remote sensing products (e.g. CORINE land cover, GMES products)
- Topographic survey products for local scale, perhaps down to cadastral units

Schematic Dipiction of exposure assessment

Approach

- Procedural Steps:
 - Calculation of population density – on residential / settlement areas only!
 - GIS intersection of inundation area (classes) and settlement areas
 - Summarize
- Example City of Meißen:
 - Population: 28780 (2002)
 - Total area: 30,7 km²
 - Population density “raw”: 937 persons / km²
 - Total settlement area: (ATKIS): 6,8 km²
 - Population density “modified”: 4230 / km²!

CHAN

Calculation Example

- Meißen:

- Settlement area: 6.8 km²
- Of this area affected by flooding 1.56 km²
- Portion: ca. 23%

- -> potentially affected by flooding:

Modified density * affected area = 4230 * 1.56 = rd. 6 600 Pers.

alternativ: 23 % of the total population: $23/100 * 28780 = \text{rd. } 6\,600 \text{ Pers.}$

Berechnung betroffene/gefährdete Personen

Tabelle 5: Betroffene und davon gefährdeten Personen (in Tausend)

Sachsen

		davon gefährdete
--	--	------------------

Ein

Tabelle 2: Möglicherweise betroffene Personen

Rhein

Rheinabschnitt	Betroffene Personen	davon Gefährdete Personen
	auf Überschwemmungsflächen	ab Wassertiefe > 200 cm
Hochrhein	7.400	100
Oberrhein	777.400	322.400
Mittelrhein	73.300	45.200
Niederrhein	1.264.200	557.400
Rheindelta	8.564.000	4.576.900
Summe	10.686.300	5.502.000

Calculation of potential damage:

- Procedure for direct economic damages
- Required data
 - Information on assets, generalized or detailed
 - Information on land use
 - Information on land use / land cover
 - Flood hazard map (inundation areas), perhaps with different probability of flooding (2yr, 5yr, 10yr, 100yr-flood etc.)
- Damage function (vulnerability curves...)
- Methods can be based on an area approach or on an object approach

Damage functions

- Grade of damage in relation to intensity of a hazard
- Intensity can be determined by:
 - Inundation depth
 - Flow velocity
 - ...
- Mainly empirical functions

Damage functions

- Must be considered in relation to the land use and asset data set on which they are applied
- Also can be influenced by additional parameters:
 - Warning time
 - Duration of flooding
 - Age of building
 - Flood protection measures

Calculation of damage potentials

- Usually no damage
- No damage

Inundated areas

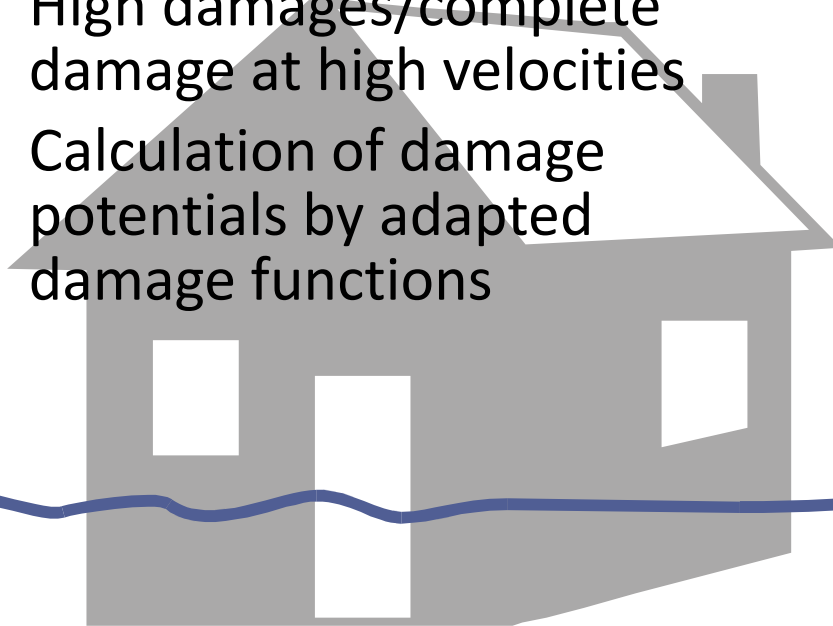

Calculation of damage potentials

- No or small damage at low flow velocities
- No damage at low velocities

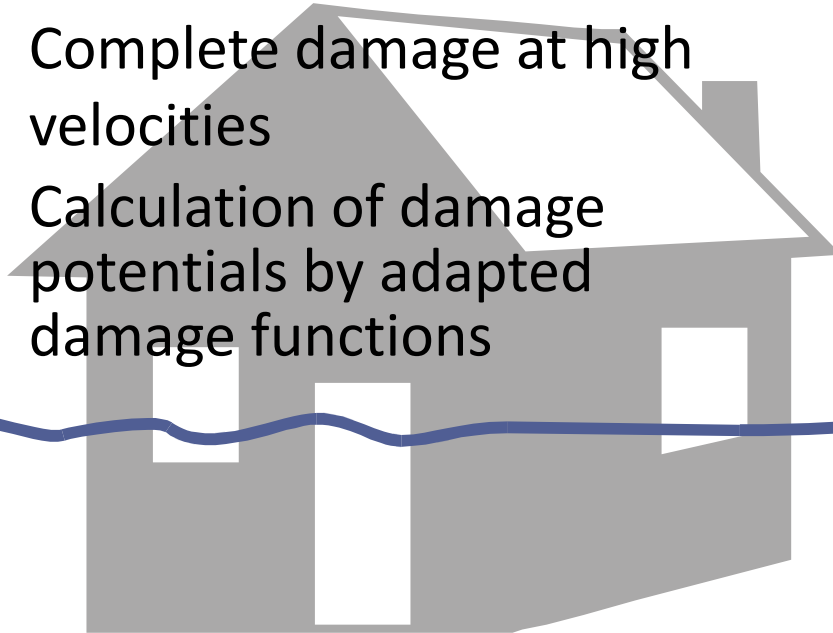

Calculation of damage potentials

- Low damages at low velocities
- High damages/complete damage at high velocities
- Calculation of damage potentials by adapted damage functions
- Potential complete damage

Calculation of damage potentials

- Low to moderate damages at low velocities
- Complete damage at high velocities
- Calculation of damage potentials by adapted damage functions
- Complete loss

Calculation of damage potentials

- Complete loss
- Complete loss

Damage functions - lowland rivers

Damage functions - steep terrain rivers

Application in GIS

- Discontinuous Urban Fabric

- Size: 150 000 m²
- NUTS2: Castilla-La Mancha
- Size of the hazard area: 75 000 m²
- Building Asset (privat): 37.81 €/m²
- Household asset (privat): 23.2 €/m²

- Exposed Asset:

$$75\,000\text{m}^2 * 37.81\text{ €/m}^2 \Rightarrow 2\,835\,750\text{ €}$$

- Exposure household assets:

$$75\,000\text{m}^2 * 23.2\text{ €/m}^2 \Rightarrow 1\,740\,000\text{ €}$$

- DF buildings: 10% \Rightarrow 283 575 €

- DF household: 25% \Rightarrow 435 000 €

- Potential Damage: 718 575 €
for this scenario

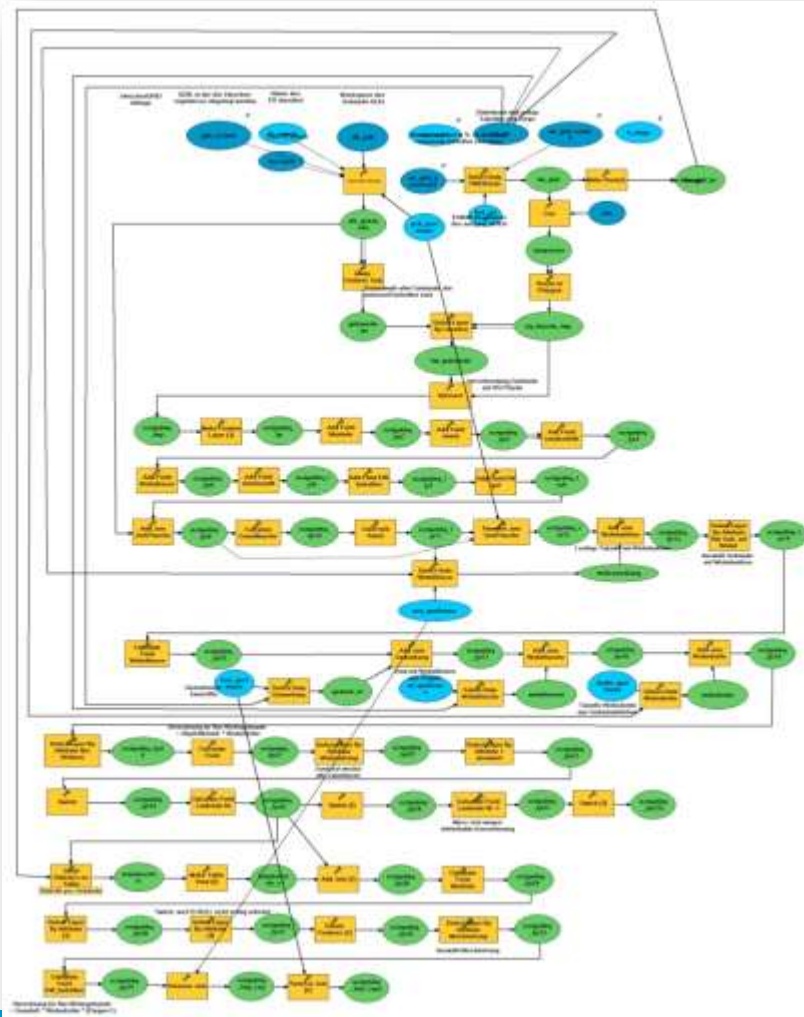

Damage functions

Relation between water depth and rate of damage
Needs to be adjusted to each land use data set
