# DANGER MAPS: CONCEPTS COMMON TO ALL PROCESSES

## Return period (T)

Mean time between two exceeds of a threshold value (or two occurrences of an event)

UNIL

## Frequency vs. probability

**Frequency** is the inverse of the return period. Its unity is usually year<sup>1</sup>, which corresponds to the average number of event per year.

**Probability** is the estimation of the likelihood of an event occurring (a given number of time) in a period of time. It is a number between 0 and 1.

If the events occurs independently according to a mean number  $\lambda$  in the interval, the probability that k events occurs in this interval is given by

$$P(X=k) = e^{-\lambda} \frac{\lambda^{\kappa}}{k!}$$

Which means that the probability that an event which occurs on average once year, do not happen in a year is 36.8%

## Statistics of extreme events

To estimate the frequency of a rare event, statistical distributions, such as Gumbel, Pareto, GEV... are used. On the opposite as the normal distribution, for example, these distributions include rare and extreme events.

In this example, the frequency of the 2 day precipitation event responsible for the 2005 flood event in Switzerland is estimated at 77 years (with an uncertainty) according to a Gumbel distribution.

# Indicative hazard maps

swisstopo dépourvues de foi publique

Indicative hazard maps are established to identify the regions were a danger map is necessary.

They are based on simple models applied with a conservative approach (i.e. to identify the maximal extent) and don't identify the intensities or probabilities

Snow avalanche indicative hazars map, geoplanet.vd.ch

Cne d'Ormont-

## The danger maps products

**Phenomenon map**: field map showing the observed phenomenon (deposited blocks,...) and the relevant objects for the process (bridges,...)

Events registry: database of all known historical events

**Scenarios**: description of the considered scenarios for each return period class

#### Models

**Intensity map**: map showing the intensity according to the 3 classes, for each scenario

**Danger map**: combination of the (3) intensity maps with the matrix symbology

# Phenomenon map

# Analysis of potential events at watershed scale

Primary processes (at the origin of the flood):

- (1) Material mobilization area
- (2) Failure of retention structures
- (3) Sedimentation
- (4) Obstruction by bridges
- (5) Obstruction of pipes
- (6) Seepage and dam failure by internal erosion
- (7) Banks overflow
- (8) Dike break after overflow
